

Non-parametric empirical heuristic-ensemble method

*Players decide how much to contribute (0, 2, or 4 MU)
by integrating four behavioural heuristics.*

Each heuristic suggests a contribution for the next round:

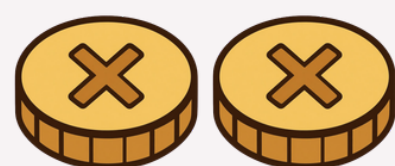

Decision vector: $\left[\begin{array}{|c|c|c|c|} \hline 2 & 4 & 2 & 0 \\ \hline \end{array} \right]$

Apply plurality voting rule:

- If two or more heuristics suggest the same contribution → choose that contribution.
- If there is a tie between different contributions → choose randomly.

Final contribution chosen:

2 MU (since H_{self} and H_{fund} agree)
